# 1 Home Page

The Home page serves as the main landing screen for the application and is built using a functional React component with TailwindCSS for styling. It features a gradient background, a hero-style welcome message, and three informational cards describing the app's features. Navigation is handled using React Router's useNavigate() function, allowing users to move to either the Login or Signup pages instantly without reloading the browser. This page establishes the overall visual style of the project, setting the tone for the clean, modern interface across all other screens.

# 2 Sign-Up

The Signup page implements a complete user registration form using React's state management. It includes fields for username, email, password, and confirm password, each tied to controlled inputs. The component performs validation—checking minimum lengths, email formatting, and password matching—before allowing the simulated submission to continue. Styled using TailwindCSS, the page features a centered card layout with gradients and hover animations to match the aesthetic of the Login and Home pages. This creates a consistent authentication flow and prepares the interface for eventual integration with a backend service.

# 3 Log-in

The Login page provides a streamlined interface for user authentication. It collects a username/email and password using controlled input fields and uses React state to manage a loading animation when the form is submitted. The form prevents default browser reloads and simulates a login process by briefly waiting before logging the input data for testing. Its design mirrors the Signup page, featuring a card-style layout with a gradient header and responsive styling built with TailwindCSS. This maintains

visual consistency and demonstrates the core structure of the app's authentication components.

Christian Salazar - 11/19/2025

My focus is on the Login and Signup pages. I began by initializing the frontend folder using Vite and React, then connected React Router so each page could be reached through routing. During setup, I ran into issues with routing, Tailwind setup, and file structure, which led to gray screens and navigation errors when I was testing the Login implementation. I worked through each problem by checking my App component paths, cleaning my project files, and restoring my dependencies until everything loaded correctly. In short, I had to start over. Once the website was working, I got to work on styling the Login page and gave it a centered card layout with inspiration from the SkillFlix assignment. I tested the page by adding a simple Home page with a button that links to the Login route to confirm everything works. Next time I will focus on implementing the Signup page.

Christian Salazar – 11/20/2025

I built the Signup page UI as part of the frontend. I used the same environment I previously set up when doing the Login page and extended the routing so the Signup page could be accessed as its own route. Since my Login page was already working, I

reused the same structure and layout style, keeping everything consistent with the UI. I created the Signup component, added the necessary form fields, and placed the whole form inside a centered card container just like the Login page. I also verified that navigation from the Home page to the Signup route works correctly. The purpose of this page is to let new users enter their information and begin the enrollment process, and the work here continues building the overall authentication flow for the project. I took visual notes and tested the styling to make sure the page matched the look of the Login screen. Next steps will involve refining the form layout and preparing both pages for eventual connection to backend logic in future development.

Alexander Tran – 11/22/2025

I built the home page from the skeleton left behind for it. I did the functionality for this too since I figured it would be good to implement it early on. I also did the layout and styling behind all the pages, keeping the functionality Christian left behind for both the sign up and login. I wanted to use the style and layout behind the HonestCritic website for the sign in and layout boxes since I figure that these will be used in our HonestCritic website at some point. I also wanted to get some more niche functionality like checks for a "valid" username, email, and password. I also added a navigation bar file in /src/components since the frontend folder was given to us as void. I did want to test out some highlighting features (as you look through the images, take note about how the navbar will highlight whatever page I am on respectively.) depending on what page you were on, with the navbar that I wanted to use for HonestCritic as well. I personally have nothing to note about the design itself, considering it is made with the idea that I will be using this on my final website, so therefore it matches the style of my website.
